# **ABSTRACT**

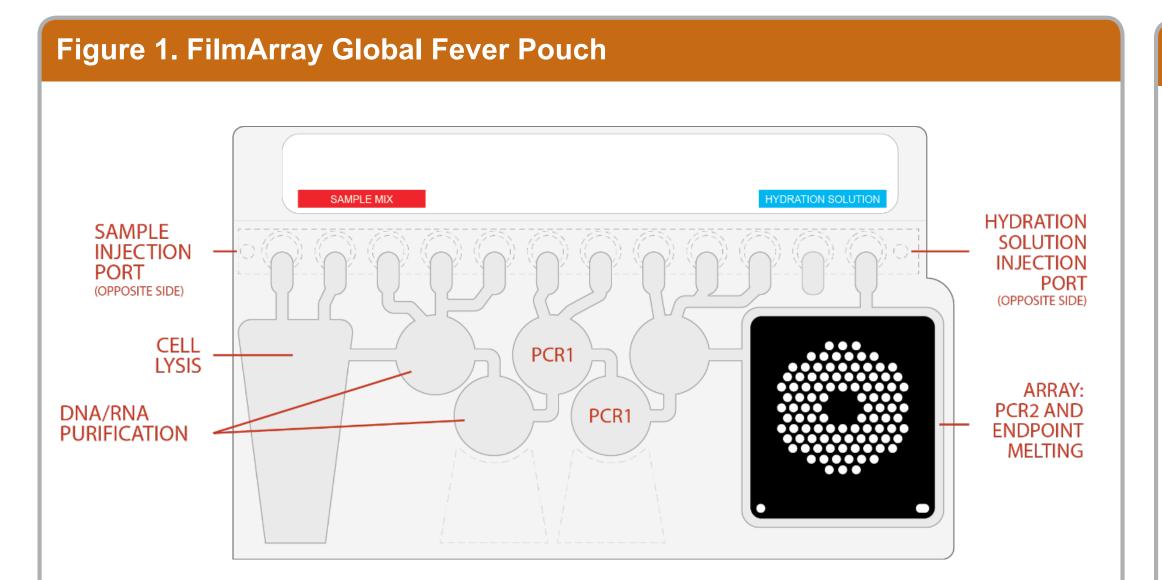

Acute Febrile Illness (AFI) can be caused by a large number of pathogens that include bacteria, viruses and parasites. BioFire Defense is developing the Global Fever (GF) Panel to be used on the FilmArray System in collaboration with the Department of Defense<sup>a</sup> and NIAID<sup>b</sup>. The FilmArray is an in vitro diagnostic test platform that combines nucleic acid purification and nested multiplex PCR for the simultaneous identification of many infectious agents in under an hour using a closed, sample-to-answer system. The FilmArray GF Panel detects and identifies nucleic acid from chikungunya virus, CCHF virus, dengue virus (serotypes 1-4), Ebola virus, Lassa virus, Marburg virus, West Nile virus, yellow fever virus, Zika virus, Bacillus anthracis, Francisella tularensis, Leptospira spp., Salmonella enterica serovar Typhi and Paratyphi A, Yersinia pestis, Leishmania donovani complex, and Plasmodium spp. in venous blood specimens from individuals with signs and/or symptoms of AFI or recent AFI and with known or suspected exposure to target pathogens. Estimated LoD studies demonstrate clinically relevant detection levels and exclusivity testing shows high specificity.

For example, estimated LoD levels for the following organisms: dengue virus New Guinea C at 36 copies/ mL, Marburg virus Ravn at 26 copies/mL, Zika virus at 130 copies/mL, Leishmania donovani at 10 copies/ mL, Plasmodium at 7 copies/mL, Bacillus anthracis at 640 copies/mL, and Yersinia pestis at 150 copies/ mL.° Preliminary off-panel exclusivity studies assessing specificity with closely related organisms or organisms that may be found in whole blood show no significant cross-reactivity. A multiplex FilmArray panel could aid in rapid and actionable AFI diagnosis.

- a. JPEO-MCS and USAMMDA Contract No. W911QY-13-D-0080, under the NGDS program.
- b. NIAID Contract No. HHSN272201600002C, "Advanced Development of Multiplex Diagnostic Platforms for Infectious Diseases (Global Fever Panel)".
- c. Estimated LoD levels updated to reflect the most recent data.

### INTRODUCTION

The FilmArray Global Fever (GF) Panel is currently under development as a qualitative, multiplexed, nucleic acid-based test intended for use with the FilmArray 2.0 system. The FilmArray Global Fever Panel detects and identifies bacterial, viral, and protozoan nucleic acids directly from human whole blood (EDTA) collected from individuals with signs and/or symptoms of acute febrile illness or recent acute febrile illness and with known or suspected exposure to target pathogens. The following organisms are detected using the FilmArray GF Panel: Bacillus anthracis, Francisella tularensis, Leptospira spp., Salmonella enterica serovar Paratyphi, Salmonella enterica serovar Typhi, Yersinia pestis, chikungunya virus, Crimean-Congo hemorrhagic fever virus, dengue virus, Lassa virus, Marburg virus, West Nile virus, yellow fever virus, Zika virus, Leishmania spp., and Plasmodium spp. (including species differentiation of *Plasmodium falciparum* from *Plasmodium vivax* and *Plasmodium ovale*).

The FilmArray Global Fever pouch is a closed system disposable that stores all the necessary reagents for sample preparation, reverse transcription, polymerase chain reaction (PCR), and detection in order to isolate, amplify, and detect nucleic acid from multiple pathogens within a single clinical whole blood specimen. After sample collection, the user injects hydration solution into one side of the pouch and sample combined with sample buffer into the other side of the pouch, places the pouch into a FilmArray instrument, and starts a run. Loading the pouch takes about 2 minutes, and the entire run process takes about an hour.

During a run, the FilmArray system:

Lyses the sample by agitation (bead beading).

sequences within the PCR1 products.

- Extracts and purifies all nucleic acids from the sample using magnetic bead technology. Performs nested multiplex PCR by:
- o First performing a single, large volume, highly multiplexed first-stage PCR reaction
- Then performing multiple, singleplex second-stage PCR reactions (PCR2) to amplify
- Uses endpoint melting curve data to detect and generate a result for each target on the FilmArray Global Fever array.

## **ESTIMATED LIMIT OF DETECTION**

The purpose of this study is to determine the estimated Limit of Detection (LoD) for the FilmArray Global Fever Panel using a collection of representative organisms covering each test result. LoDos is defined as the lowest concentration of organism that can be consistently detected by the panel; analyte is detected in at least 19/20 samples (≥ 95% detected). An initial Estimated LoD (Table 1) is established using serial 10-fold dilutions. The Estimated LoD is the lowest concentration at which 3/3 replicates returned a Detected result. Samples are prepared in whole blood obtained from a repository, Bioreclamation IVT.

The estimated LoD is determined for the FilmArray Global Fever Panel test results using 'primary' analytes.

# **EXCLUSIVITY**

To determine whether the FilmArray Global Fever Panel assays cross-react with sequences from various microorganisms/viruses that may be present in clinical specificity of the panel was assessed by in silico analysis and by testing a broad spectrum of organisms/viruses at high concentrations. Typical stock concentrations for on-panel analytes tested are: 107-1010 copies/mL for bacteria, 107-109 copies/mL for virus, and 106-108 copies/mL for virus, and 106-108 copies/mL for virus, and 106-108 copies/mL for bacteria, 107-109 copies/mL for virus, and 106-108 copies/mL for we report a subset of off-panel testing.

• On-panel testing consists of contrived samples spiked into sterile saline with the highest concentration of the total sample volume). On-panel isolates are the same as those evaluated for the estimated LoD study. • Off-panel organisms are selected based on 1) phylogenetic and/or genetic similarity to the possibility that the organism(s) could be present as normal flora, contaminants associated with sample collection, or pathogens in whole blood.

#### **INCLUSIVITY**

the analytical reactivity of the assays was evaluated by testing multiple isolates per analyte. Isolates are selected based on the availability of live and inactivated stocks, genetic, temporal and geographic diversity, and clinical relevance of the various species, strains, subspecies, serotypes, genotypes and genetic variants available for testing. In addition, in silico data (sequence searches and alignments to assay primers) are also used to support the inclusivity of the FilmArray Global Fever Panel assays. Here we present a subset of inclusive organisms tested. Samples are prepared by spiking analytes into whole blood from healthy donors (obtained from Bioreclamation IVT repository) at a concentration near 3× estimated LoD. Figure 2 depicts the protocol followed to establish inclusivity of the isolates tested. An initial subset of analytes tested on

To ensure the Global Fever Panel is inclusive for the genetic variation expected for each analyte,

Detected Rate 3/3 or 4/5 at 100× LoD Yes\* -> Inclusivity Demonstrated No → Research Potential Cause(s)

 May have decreased sensitivity, further investigation may be needed.

## **SUMMARY**

The development of a multiplex FilmArray panel would aid in rapid and actionable AFI diagnosis The GF Panel provides a broad spectrum analysis of target pathogens in a sensitive and specific

- Estimated LoD values show sensitivity levels at or below clinically relevant concentrations
- On- and off-panel exclusivity show no evidence of cross-reactivity.
- Preliminary inclusivity maintains expected coverage of relevant target pathogens.
- Preparing for full analytical and clinical studies for the FilmArray GF Panel.

\* Samples of P. ovale are currently unavailable. Efforts are in progress to acquire clinical samples of P. ovale
